### **ABSTRACT**

A single individual marine gastropod species was collected by harbor survey (Seoqwipo port) and was identified as *Antillophos nigroliratus* (Habe, 1961). To date, 24 species from five genera and three subfamilies in the family Nassariidae have been recorded in Korea. In this study, we provide descriptions and photographs of *A. nigroliratus* as a new record in Korean waters.

**Keywords:** New record, Antillophos nigroliratus, Harbor survey, Korea

# INTRODUCTION

The family Nassariidae, commonly known as mud snails or dog whelks, is predominantly composed of small-size marine gastropod. It is found throughout worldwide oceans, tropical, temperate and cold waters (Cernohorsky, 1972; Nekhaev, 2014; Galinodo *et al.*, 2016). Members of family Nassariidae mostly occur in intertidal soft sandy and muddy habitats, although some species have been found in deep waters (Cernohorsky, 1972; Nekhaev, 2014; Galinodo *et al.*, 2016). They are a group of scavengers that play an important role in the balance of the benthic communities (Zou *et al.*, 2012).

According to the WoRMS 2015 data, over 2,500 nominal nassariids, including 1,320 extant and 1,180 fossils, have been established. They are divided into 4 subfamilies, 12 genera and 25 subgenera traditionally (Allmon, 1990; Cernohorsky, 1984; Galinodo *et al.*,

2016; Haasl, 2000; Kantor and Kilburn, 2001; Pastorino, 1993). Based on recent molecular analysis of the Nassariidae, several genera (Anentome, Antillophos, Engoniophos, Macron, Nassaria, Northia, Neoteron, Trajana and Phos) of Buccinidae have been transferred to the Nassariidae (Galinodo et al., 2016). In Korea, 24 species from 5 genera and 3 subfamilies in the family Nassariidae have been recorded (Choe, 1992; Lee, 2016; Lee and Min, 2002; Min et al., 2004; NIBR, 2019).

In this study, a specimen was collected by harbor survey in Seogwipo port, from a fishing boat which using a trawl net offshore around Jeju Island, Korea. The morphological feature of this specimen was examined using a stereomicroscope (Leica, MZ12.5, Germany). Based on its shell characters, this specimen was identified as *Antillophos nigroliratus* (Habe, 1961), the first record from Korean waters. The specimen was deposited at National Marine Biodiversity Institute of Korea (MABIK), Seocheon, Republic of Korea.

**Type locality**: Off Isshiki-cho, Hazu-gun, Aichi Pref., Honshu, Japan (Habe, 1961).

**Habitat**: Sandy gravel or muddy bottoms, 50-200 m deep.

**Distribution**: Japan (Habe, 1961; Okutani, 2000), Philippines (Cernohorsky, 1987; Poppe, 2008), and Korea (Jeju Island, this study).

Material examined: 1 specimen (MABIK MO00175232), Seogwipo port, Seogwipo-si, Jeju-do, 28 July 2019, S-H. Lee. Measurement: Shell height 42 mm; shell width 17 mm. Description: Shell small, slender fusiform with low spire. Whorls 8-9 in number with deep sutures and spire approximately 1/2 of shell height. Shell surface light yellowish with red-brown thin band on whorls. Protoconch small, conical, apex eroded with blackish navy. Teleoconch whorls sculptured with closely spaced low axial ribs, with 7-9 short keels on spire. Intersections of oblique axial ribs and spiral sculpture with nodules. Aperture auriform, outer lip thick and

strong, inside white with spiral lirae. Columella straight and short, covered with callous. Siphonal canal straight and short, opened.
